( hjhe@tsinghua.edu.cn and xunjie.xu@gmail.com )

Leptonic unitarity triangle (LUT) provides fundamental means to geometrically describe CP violation in neutrino oscillation. In this work, we use LUT to present a new geometrical interpretation of the vacuum oscillation probability, and derive a compact new oscillation formula in terms of only 3 independent parameters of the corresponding LUT. Then, we systematically study matter effects in the geometrical formulation of neutrino oscillation with CP violation. Including nontrivial matter effects, we derive a very compact new oscillation formula by using the LUT formulation. We further demonstrate that this geometrical formula holds well for applications to neutrino oscillations in matter, including the long baseline experiments T2K, MINOS,  $NO\nu A$ , and DUNE.

#### I. Introduction

Discovering leptonic CP violation poses a major challenge to particle physics today, and may uncover the origin of matter-antimatter asymmetry in the Universe [\[1\]](#page-7-0). Unitarity triangles provide the unique geometrical description of CP violations via  $3 \times 3$  unitary matrix. They have played a vital role for studying CP violation of Cabibbo-Kobayashi-Maskawa (CKM) mixings in the quark sector [\[2\]](#page-8-0). So far various neutrino oscillation experiments have been trying to precisely measure Pontecorvo-Maki-Nakagawa-Sakata (PMNS) mixings for the lepton-neutrino sector [\[3\]](#page-8-1). Leptonic unitarity triangles (LUT) provide a fundamental means to probe the leptonic CP violation, complementary to the usual method of measuring the CP asymmetry of neutrino oscillations,  $P[\nu_{\ell} \to \nu_{\ell'}] - P[\bar{\nu}_{\ell} \to \bar{\nu}_{\ell'}]$  ( $\ell \neq \ell'$ ) [\[4,](#page-8-2) [5\]](#page-8-3). Some LUT studies appeared in the recent literature [\[6](#page-8-4)[–9\]](#page-8-5).

In Ref. [\[6\]](#page-8-4), we found that LUT is directly connected to neutrino oscillations in vacuum. We proved [\[6\]](#page-8-4) that the LUT angles exactly act as the CP-phase shifts of neutrino oscillations. We proved [\[6\]](#page-8-4) that vacuum oscillation only depends on 3 independent geometrical parameters of the corresponding LUT. Because matter effects [\[10,](#page-8-6) [11\]](#page-8-7) in many current and future long baseline (LBL) oscillation experiments (such as T2K [\[12\]](#page-8-8), MINOS [\[13\]](#page-8-9),  $NO\nu A$  [\[14\]](#page-8-10), and DUNE [\[15\]](#page-8-11)) are non-negligible, it is important to develop our geometrical LUT formulation for including nontrivial matter effects.

In this work, we construct a new unified geometrical LUT formulation for neutrino oscillations in vacuum and in matter, and study its applications. In Sec.[II,](#page-0-0) we present a new geometrical LUT formulation to dynamically describe how 3-neutrino system oscillates in vacuum. From this, we derive a new compact oscillation formula, manifestly in terms of only 3 independent parameters of the corresponding LUT. In Sec.[III,](#page-2-0) we systematically study the LUT formulation for neutrino os-

<span id="page-0-1"></span>Figure 1: The leptonic unitarity triangle (LUT), where  $\ell \neq$  $\ell'$ ,  $(a, b, c)$  denote lengths of the three sides, and  $(\alpha, \beta, \gamma)$ represent the three angles.

cillations in matter. We derive an approximate analytical LUT formula including matter effects, and further analyze its accuracy for the current and future long baseline oscillation experiments, in Sec.[IV](#page-3-0) and Appendix [A-](#page-5-0)[B.](#page-7-1) Finally, we conclude in Sec. [V.](#page-5-1)

### <span id="page-0-0"></span>II. Geometrical Formulation of Neutrino Oscillation in Vacuum

From the unitarity of PMNS matrix,  $U^{\dagger}U = U U^{\dagger} = 1$ , we have two sets of conditions,  $\sum_j U_{\ell j} U^*_{\ell' j} = 0$  with  $\ell \neq \ell'$  (forming the row triangles or "Dirac triangles"), and  $\sum_{\ell} U_{\ell j}^* U_{\ell j'} = 0$  with  $j \neq j'$  (forming the column triangles or "Majorana triangles"). For the flavor neutrino oscillations, we consider the Dirac triangles  $(\ell \neq \ell')$ ,

<span id="page-0-3"></span><span id="page-0-2"></span>
$$
U_{\ell 1} U_{\ell' 1}^* + U_{\ell 2} U_{\ell' 2}^* + U_{\ell 3} U_{\ell' 3}^* = 0, \qquad (1)
$$

as shown in Fig[.1.](#page-0-1)

The sides and angles of each LUT [\(1\)](#page-0-2) can be defined,

<span id="page-0-4"></span>
$$
(a, b, c) = (|U_{\ell 1} U_{\ell' 1}^*|, |U_{\ell 2} U_{\ell' 2}^*|, |U_{\ell 3} U_{\ell' 3}^*|), \tag{2a}
$$

$$
(\alpha, \beta, \gamma) = \arg \left( -\frac{U_{\ell 3} U_{\ell' 3}^*}{U_{\ell 2} U_{\ell' 2}^*}, -\frac{U_{\ell 1} U_{\ell' 1}^*}{U_{\ell 3} U_{\ell' 3}^*}, -\frac{U_{\ell 2} U_{\ell' 2}^*}{U_{\ell 1} U_{\ell' 1}^*} \right). (2b)
$$

In Ref. [\[6\]](#page-8-4), we proved that the conventional neutrino oscillation probability in vacuum [\[4\]](#page-8-2)[\[5\]](#page-8-3) can be fully expressed in terms of the sides  $(a, b, c)$  and angles  $(\alpha, \beta, \gamma)$  of the corresponding LUT, among which only 3 are independent.

In the following, we propose a new geometrical approach. With this, we will derive a new formula of vacuum oscillations, which manifestly contains only 3 independent parameters of the LUT for each given channel, say  $(b, c, \alpha)$ , and takes a very compact form.

In the standard formulation, the neutrino oscillation in space may be described by the following Schrödinger-like evolution equation in flavor basis,

<span id="page-1-0"></span>
$$
\mathbf{i}\frac{\mathrm{d}}{\mathrm{d}L}|\nu(L)\rangle = H|\nu(L)\rangle,\tag{3}
$$

where H is the effective Hamiltonian and  $|\nu(L)\rangle$  denotes the flavor state of the flying neutrino at a distance L from the source. In vacuum, we can write the effective Hamiltonian  $H_0$  in the following matrix form,

<span id="page-1-6"></span>
$$
H_0 = \frac{1}{2E} U \begin{pmatrix} m_1^2 & & \\ & m_2^2 & \\ & & m_3^2 \end{pmatrix} U^{\dagger}.
$$
 (4)

Solving Eq.[\(3\)](#page-1-0) gives,  $|\nu(L)\rangle = e^{-iH_0L}|\nu(0)\rangle$ . So, the transition amplitude of  $\nu_{\ell} \to \nu_{\ell'}$  takes the form,  $A_{\ell \to \ell'} = \sum_j U_{\ell j} U^*_{\ell' j} e^{i2\Delta_j}$ , where  $\Delta_j \equiv m_j^2 L/(4E)$ . Thus, we deduce the oscillation probability  $P_{\ell \to \ell'} = |A_{\ell \to \ell'}|^2$  as,

<span id="page-1-1"></span>
$$
P_{\ell \to \ell'} = |U_{\ell 1} U_{\ell' 1}^* e^{i2\Delta_1} + U_{\ell 2} U_{\ell' 2}^* e^{i2\Delta_2} + U_{\ell 3} U_{\ell' 3}^* e^{i2\Delta_3}|^2
$$
  
=  $|a + b e^{i(\gamma - \pi)} e^{i2\Delta_{21}} + c e^{i(\pi - \beta)} e^{i2\Delta_{31}}|^2,$  (5)

where in the second row we have used Eq.[\(2\)](#page-0-3), and  $\,\Delta_{jk}\equiv\,$  $\Delta m_{jk}^2 L/(4E)$  with  $\Delta m_{jk}^2 = m_j^2 - m_k^2$   $(j, k = 1, 2, 3)$ .

We inspect Eq. [\(5\)](#page-1-1) and find a new way to demonstrate its geometry graphically. For  $L/E = 0$ , we have  $P_{\ell \to \ell'} = 0$  and  $\Delta_{21} = \Delta_{31} = 0$ . Hence, under  $L/E = 0$ ,  $Eq.(5)$  $Eq.(5)$  reduces to

<span id="page-1-3"></span>
$$
a + b e^{i(\gamma - \pi)} + c e^{i(\pi - \beta)} = 0.
$$
 (6)

This just corresponds to the geometry of the LUT  $\triangle ABC$ shown in Fig. [1.](#page-0-1) We re-present this picture in Fig. [2,](#page-1-2) where we have  $(|BC|, |CA|, |AB|) = (a, b, c)$ , and  $(\angle CAB, \angle ABC, \angle BCA) = (\alpha, \beta, \gamma)$ . We see that the triangle geometry  $\overrightarrow{BC} + \overrightarrow{CA} + \overrightarrow{AB} = 0$  just gives the equality [\(6\)](#page-1-3).

The generical case of  $L/E \neq 0$  has nonzero oscillation factors  $e^{i2\Delta_{21}}$  and  $e^{i2\Delta_{31}}$ . This will modify the equality [\(6\)](#page-1-3), in which  $e^{i(\gamma - \pi)}$  is replaced by  $e^{i(\gamma - \pi)}e^{i2\Delta_{21}}$ , and  $e^{i(\pi-\beta)}$  by  $e^{i(\pi-\beta)}e^{i2\Delta_{31}}$ , causing the nonzero proba-bility [\(5\)](#page-1-1). Geometrically, the phase factors  $e^{i2\Delta_{21}}$  and  $e^{i2\Delta_{31}}$  will change orientations of vectors  $\overrightarrow{CA}$  and  $\overrightarrow{BA}$  by holding their lengths. This will rotate  $\overrightarrow{CA}$  to  $\overrightarrow{CE}$ , and  $\overrightarrow{BA}$  to  $\overrightarrow{BF}$ , both counterclockwise. Denoting the angles

<span id="page-1-2"></span>Figure 2: New geometrical presentation of neutrino oscillation, where the angles  $\angle ABF = \varphi_1$  and  $\angle ACE = \varphi_2$  are evolving phases  $\varphi_1 = L \Delta m_{31}^2/(2E)$  and  $\varphi_2 = L \Delta m_{21}^2/(2E)$ in Eq. [\(7\)](#page-1-4). The squared-distance  $|EF|^2$  just gives the oscillation probability  $(5)$  via Eqs. $(9)$  and  $(12)$ . If the triangle is closed,  $|EF| = 0$  and the probability vanishes. When L increases, the Point-E and Point-F will circle around the corresponding dashed arcs, and the distance  $|EF|$  oscillates. This means that the transition probability oscillates.

 $\angle ABF = \varphi_1$  and  $\angle ACE = \varphi_2$ , we have the following relations,

<span id="page-1-4"></span>
$$
\varphi_1 = 2\Delta_{31}, \qquad \varphi_2 = 2\Delta_{21}.\tag{7}
$$

This shows that the triangle is unfolded to become a quadrangle  $ECBF$ , and the side  $EF$  just equals the amplitude,

$$
\overrightarrow{EF} = a + be^{i(\gamma - \pi)}e^{i2\Delta_{21}} + ce^{i(\pi - \beta)}e^{i2\Delta_{31}}.
$$
 (8)

Comparing this with Eq. [\(5\)](#page-1-1), we conclude that

<span id="page-1-5"></span>
$$
|EF|^2 = P_{\ell \to \ell'}, \tag{9}
$$

just gives the oscillation probability. When the quadrangle ECBF reduces to a closed triangle  $\triangle ABC$ , the oscillation probability would vanish. When  $L/E$  increases, the Point- $E$  and Point- $F$  in Fig. [2](#page-1-2) will circle around the corresponding dashed arcs. Thus, the distance  $|EF|$  oscillates, and its square  $|EF|^2$  exactly equals the oscillation probability  $(5)$  via Eq. $(9)$ . Hence, we have demonstrated that Fig. [2](#page-1-2) and Eq.[\(9\)](#page-1-5) give a new geometrical presentation of neutrino oscillations in vacuum.

We can directly compute the oscillation probability by using the above geometrical formulation. As will be shown below, it is striking that using this geometrical formulation, we can derive a very compact new formula of neutrino oscillations, manifestly in terms of only 3 LUT parameters. Without losing generality, we assign  $\overrightarrow{CA}$  as the x-axis and its orthogonal direction as y-axis. Thus, we can derive the following coordinates for points  $E$  and  $F$  in the x-y plane,

E: 
$$
(b \cos \varphi_2, b \sin \varphi_2),
$$
  
\nF:  $\left(b - 2c \sin \frac{\varphi_1}{2} \cos \angle FAC, -2c \sin \frac{\varphi_1}{2} \sin \angle FAC\right),$  (10)

where the angle  $\angle FAC = \alpha + \frac{1}{2}(\varphi_1 - \pi)$ . With these, we compute the length of the line segment EF as

<span id="page-2-2"></span>
$$
|EF|^2 = 4c^2 \sin^2 \frac{\varphi_1}{2} + 4b^2 \sin^2 \frac{\varphi_2}{2}
$$

$$
-8bc \sin \frac{\varphi_1}{2} \sin \frac{\varphi_2}{2} \cos \left(\frac{\varphi_1 - \varphi_2}{2} + \alpha\right).
$$
 (11)

Using Eqs. $(7)$ ,  $(9)$ , and  $(11)$ , we derive an elegant and very compact new formula of vacuum oscillations,

<span id="page-2-1"></span>
$$
P_{\ell \to \ell'} = 4c^2 \sin^2 \Delta
$$
  
-8bc sin $\Delta$  sin  $\epsilon \Delta$  cos[(1 -  $\epsilon$ ) $\Delta$  +  $\alpha$ ] (12)  
+4b<sup>2</sup> sin<sup>2</sup> $\epsilon \Delta$ ,

where we have defined,

<span id="page-2-3"></span>
$$
\Delta \equiv \Delta_{31} = \frac{\Delta m_{31}^2 L}{4E}, \quad \epsilon \equiv \frac{\Delta_{21}}{\Delta_{31}} = \frac{\Delta m_{21}^2}{\Delta m_{31}^2}.
$$
 (13)

The anti-neutrino oscillation probability  $P_{\bar{\ell}\to\bar{\ell}'}$  can be obtained from Eq.[\(12\)](#page-2-1) under the replacement  $\alpha \to -\alpha$ . The new oscillation formula  $(12)$  invokes only 3 independent geometrical parameters  $(b, c, \alpha)$  of the corresponding LUT, while the other 3 non-independent parameters  $(a, \beta, \gamma)$  have been explicitly removed in Eq.[\(12\)](#page-2-1). Furthermore, this explicitly proves that the 4 PMNSparameters  $(\theta_{13}, \theta_{23}, \theta_{12}, \delta)$  could enter the oscillation probability [\(12\)](#page-2-1) only via their 3 independent combinations in terms of the geometrical parameters of LUT, such as  $(b, c, \alpha)$ . Note that Eq.[\(12\)](#page-2-1) makes no approximation. But it may be regarded as a Taylor expansion in terms of  $\sin \epsilon \Delta$  or  $\epsilon$ , which is small due to  $\epsilon \approx 0.03$  [\[16\]](#page-8-12)[\[17\]](#page-8-13) and  $\Delta \sim O(1)$  for all known accelerator oscillation ex-periments [\[12\]](#page-8-8)-[\[15\]](#page-8-11). In Eq.[\(12\)](#page-2-1), the first row is of  $O(\epsilon^0)$ , serving as the leading order (LO). The second and third rows, of  $O(\epsilon^1)$  and  $O(\epsilon^2)$ , belong to the next-to-leading order (NLO) and next-to-next-to-leading order (NNLO), respectively. No other higher order terms exist because  $Eq.(12)$  $Eq.(12)$  is exact.

Using our new Eq. $(12)$ , we can rederive the oscillation CP asymmetry  $A_{\rm CP}^{\ell\ell'} = P_{\ell \to \ell'} - P_{\bar{\ell} \to \bar{\ell}'}$ ,

<span id="page-2-4"></span>
$$
A_{\rm CP}^{\ell\ell'} = 32 S_{\triangle} \sin\Delta \sin\epsilon \Delta \sin(1 - \epsilon) \Delta
$$
 (14)  
= 
$$
4J(\sin 2\Delta_{21} + \sin 2\Delta_{13} + \sin 2\Delta_{32}),
$$

where  $(\Delta, \epsilon)$  are defined in Eq.[\(13\)](#page-2-3), and the Jarlskog in-variant J [\[18\]](#page-8-14) equals twice of the LUT area,  $J = 2S_{\wedge}$  =  $bc \sin \alpha$ . The last line of Eq.[\(14\)](#page-2-4) agrees to the conventional CP asymmetry formula [\[5\]](#page-8-3).

As a final remark, we consider the conventional vacuum oscillation formula [\[4\]](#page-8-2)[\[5\]](#page-8-3),

<span id="page-2-5"></span>
$$
P_{\ell \to \ell'} = \sum_{j=1}^{3} |U_{\ell'j} U_{\ell j}|^2 + 2 \sum_{j < k} |U_{\ell'j} U_{\ell j} U_{\ell k} U_{\ell' k}| \cos(2\Delta_{jk} \mp \phi_{\ell' \ell; jk}), \qquad (15)
$$

where the signs "∓" correspond to  $\nu_{\ell}(\bar{\nu}_{\ell})$  oscillations. Eq.[\(15\)](#page-2-5) contains the CP phase angle [\[4\]](#page-8-2)[\[5\]](#page-8-3),  $\phi_{\ell' \ell; jk}$  =  $arg(U_{\ell'j}U_{\ell j}^*U_{\ell k}U_{\ell' k}^*)$ . As we proved in Ref. [\[6\]](#page-8-4), each CPphase shift  $\phi_{\ell' \ell; jk}$  exactly equals the corresponding angle of the LUT (modulo  $\pi$ ), i.e.,  $(\phi_{\ell' \ell; 23}, \phi_{\ell' \ell; 31}, \phi_{\ell' \ell; 12}) =$  $(\alpha, \beta, \gamma) + \pi$ , where the convention of each LUT angle  $(\alpha, \beta, \gamma)$  in Eq.[\(2b\)](#page-0-4) differs from that of [\[6\]](#page-8-4) by a minus sign. With this, we derived the vacuum oscillation probability  $P[\nu_{\ell} \to \nu_{\ell'}],$  fully in terms of the geometrical parameters of the corresponding LUT [\[6\]](#page-8-4),

<span id="page-2-6"></span>
$$
P_{\ell \to \ell'} = 4ab \sin(\Delta_{12} \mp \gamma) \sin \Delta_{12}
$$
  
+ 
$$
4bc \sin(\Delta_{23} \mp \alpha) \sin \Delta_{23}
$$
  
+ 
$$
4ca \sin(\Delta_{31} \mp \beta) \sin \Delta_{31}
$$
, (16)

according to the current convention of Eq. $(2)$ . Although Eq.[\(16\)](#page-2-6) contains all 6 parameters  $(a, b, c)$  and  $(\alpha, \beta, \gamma)$ of the LUT, only 3 are independent. Hence, if we choose 3 of them, say  $(b, c, \alpha)$ , the remaining parameters  $(a, \beta, \gamma)$ can all be expressed in terms of  $(b, c, \alpha)$ ,

<span id="page-2-7"></span>
$$
a = \sqrt{b^2 + c^2 - 2bc \cos \alpha},
$$
  
\n
$$
\gamma = \arccos\left(\frac{a^2 + b^2 - c^2}{2ab}\right), \quad \beta = \pi - (\alpha + \gamma).
$$
\n(17)

We could try to eliminate the non-independent parameters  $(a, \beta, \gamma)$  by substituting Eq.[\(17\)](#page-2-7) into Eq.[\(16\)](#page-2-6). But the resultant form is very complicated and lengthy. Only after we obtain the new formula [\(12\)](#page-2-1) by the current geometrical approach  $[Fig.1 \text{ and } Eq.(9)]$  $[Fig.1 \text{ and } Eq.(9)]$ , we could use  $Eq.(12)$  $Eq.(12)$  as the final answer (guideline), and eventually reduce Eq.[\(16\)](#page-2-6) to Eq.[\(12\)](#page-2-1) after tedious derivations. Our new formula [\(12\)](#page-2-1) is important, because extending it we can further successfully construct the LUT formulation of neutrino oscillations including nontrivial matter effects, as we will present in Sec.[III](#page-2-0)[-IV.](#page-3-0)

#### <span id="page-2-0"></span>III. Neutrino Oscillations in Matter and Effective Leptonic Unitarity Triangle

Including matter effects requires to add the following new term  $H_i$  into the effective Hamiltonian H which appears in the evolution equation [\(3\)](#page-1-0),

<span id="page-2-8"></span>
$$
H_i = \sqrt{2}G_F N_e \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \tag{18}
$$

where the electron density  $N_e = (Z/A) \rho N_A$ , with  $\rho$ the matter density,  $Z(A)$  the atomic number (atomic mass number), and  $N_A$  the Avogadro constant. Eq.[\(18\)](#page-2-8) is for neutrino oscillations in matter, and for anti-neutrino oscillations the matter term [\(18\)](#page-2-8) flips sign [\[5\]](#page-8-3). Including this matter term  $(18)$ , we need to solve Eq.[\(3\)](#page-1-0) with H given by

$$
H = H_0 + H_i. \tag{19}
$$

For the current LBL experiments, neutrino beams only pass through the crust of the Earth. So  $N_e$  is well approximated as a constant. Thus, we derive the solution of  $\text{Eq.}(3), \ |\nu(L)\rangle = e^{-iHL}|\nu(0)\rangle$  $\text{Eq.}(3), \ |\nu(L)\rangle = e^{-iHL}|\nu(0)\rangle$  $\text{Eq.}(3), \ |\nu(L)\rangle = e^{-iHL}|\nu(0)\rangle$ . The Hamiltonian  $H_0$  can be diagonalized by the PMNS matrix  $U$ , but  $H$  cannot, i.e.,  $U^{\dagger}H_0U$  is diagonal, but  $U^{\dagger}HU = U^{\dagger}H_0U + U^{\dagger}H_iU$ is not. Hence, we need to rediagonalize  $H$  by an effective mixing matrix  $U_m (\equiv U + \delta U)$ , which results in the effective neutrino masses  $\tilde{m}_i$ . Thus, we have

<span id="page-3-1"></span>
$$
H = \frac{1}{2E} U_m \begin{pmatrix} \tilde{m}_1^2 & \cdots & \tilde{m}_2^2 \\ & \tilde{m}_3^2 & \cdots & \tilde{m}_3^2 \end{pmatrix} U_m^{\dagger} . \tag{20}
$$

From the effective mixing matrix  $U_m$ , we can construct the effective leptonic unitarity triangles (ELUT), in the same way as we did for analyzing the vacuum LUT in Sec. [III.](#page-2-0) When neutrino energy E is very low,  $H_0 \gg H_i$ and  $U_m$  is fairly close to U. Hence, in the limit  $E \rightarrow$ 0 , the ELUT simply reduce to the corresponding LUT. When  $E$  increases, ELUT gradually deviate from LUT since  $U_m$  deviates from U. Thus, the forms of ELUT will vary under the change of neutrino energy  $E$ .

The oscillation formula in matter is obtained by just replacing the original LUT parameters, say,  $(b, c, \alpha)$ , by the new ELUT parameters  $(b_m, c_m, \alpha_m)$ . We make the same replacements for effective neutrino masses in Eq.[\(20\)](#page-3-1).

This means that the geometrical presentation of neutrino oscillations in Fig. [2](#page-1-2) still holds after including the matter effects. The only difference is to replace the vacuum LUT by the ELUT in matter and the neutrino masses  $m_{1,2,3}$  by  $\tilde{m}_{1,2,3}$ . When a neutrino propagates in matter and its distance L increases, the Point-E and Point-F in Fig. [2](#page-1-2) will circle around the corresponding arcs in the ELUT frame. Then, the distance  $|EF|$  oscillates, and  $|EF|^2$  gives the oscillation probability in matter. Hence, including matter effects into Eq. $(12)$ , we deduce the oscillation formula,

<span id="page-3-2"></span>
$$
P_{\ell \to \ell'} = 4c_m^2 \sin^2 \Delta_m
$$
  
-8b<sub>m</sub>c<sub>m</sub> sin $\Delta_m$  sin( $\epsilon_m \Delta_m$ ) cos[(1- $\epsilon_m$ ) $\Delta_m$ + $\alpha_m$ ]  
+4b<sub>m</sub><sup>2</sup> sin<sup>2</sup>( $\epsilon_m \Delta_m$ ), (21)

where parameters with subscripts " $_m$ " denote the corresponding effective parameters in matter. For instance,  $b_m$ is the b-side of the ELUT from  $U_m$  in Eq.[\(20\)](#page-3-1).  $(\Delta_m, \epsilon_m)$ are obtained from  $(\Delta, \epsilon)$  [cf. Eq.[\(13\)](#page-2-3)] under the replacements  $m_{1,2,3} \to \tilde{m}_{1,2,3}$  [cf. Eq.[\(20\)](#page-3-1)].

Note that  $Eq.(21)$  $Eq.(21)$  is an exact formula, and so far we have not made any approximation. When neutrino energies lie between the solar resonance and atmospheric resonance,  $0.1 \,\text{GeV} \lesssim E \lesssim 3 \,\text{GeV}$  [\[19\]](#page-8-15), one has the matter density  $\rho \simeq 2.6 \text{ g/cm}^3$  [\[20\]](#page-8-16) for the earth crust, and the averaged ratio  $Z/A \simeq 1/2$ , where Z and A are the atomic number and mass number, respectively. With these, we deduce the approximate relations after a nontrivial and lengthy derivation,

<span id="page-3-3"></span>
$$
c_m \simeq \frac{c}{1 - n_E} \,, \quad b_m \simeq \frac{\epsilon b}{n_E} \,, \quad \alpha_m \simeq \alpha \pm \pi \,, \qquad (22a)
$$

<span id="page-3-4"></span>
$$
\epsilon_m \simeq \frac{-n_E}{1 - n_E}, \quad \Delta_m \simeq (1 - n_E)\Delta \,, \tag{22b}
$$

where  $n_E$  is defined as

$$
n_E = 2\sqrt{2} \, G_F N_e E / \Delta m_{31}^2 \,. \tag{22c}
$$

For clarity, we will present the nontrivial derivation of Eq.[\(22\)](#page-3-3) in Appendix [A.](#page-5-0) These are important relations connecting the ELUT parameters in matter to the corresponding LUT parameters in vacuum. They allow us to use the vacuum LUT parameters to directly compute the oscillation probability in matter. This makes our LUT formulation applicable to the current and future LBL oscillation experiments [\[12\]](#page-8-8)-[\[15\]](#page-8-11). In the following Sec.[IV](#page-3-0) as well as Appendix [B,](#page-7-1) we will perform numerical analysis to explicitly test the accuracy of the above matter formulas [\(21\)](#page-3-2)-[\(22\)](#page-3-3), and discuss their validity.

### <span id="page-3-0"></span>IV. Applications: Testing the Precision of Geometrical Oscillation Formula

So far, most of the LBL experiments measure neutrino appearance via the oscillation channel  $\nu_{\mu} \rightarrow \nu_{e}$ . Using our general geometrical equation [\(21\)](#page-3-2) together with the approximate relations [\(22a\)](#page-3-4)-[\(22b\)](#page-3-4), we derive the following analytical LUT formula for the appearance oscillation probability,

<span id="page-3-5"></span>
$$
P_{\text{LUT}}(\nu_{\mu} \to \nu_{e}) =
$$
  
\n
$$
\frac{4c^{2}}{(1-n_{E})^{2}} \sin^{2}[(1-n_{E})\Delta] + \frac{4\epsilon^{2}b^{2}}{n_{E}^{2}} \sin^{2}(n_{E}\Delta)
$$
  
\n
$$
-\frac{8ebc\sin[(1-n_{E})\Delta]\sin(n_{E}\Delta)\cos(\Delta+\alpha)}{n_{E}(1-n_{E})}.
$$
 (23)

The anti-neutrino oscillation probability  $P_{\text{LUT}}(\bar{\nu}_{\mu} \rightarrow$  $\bar{\nu}_e$ ) is obtained from Eq.[\(23\)](#page-3-5) under the replacement  $(\alpha, n_E) \rightarrow (-\alpha, -n_E)$ . We stress that the new formula [\(23\)](#page-3-5) is fully expressed in terms of only 3 independent parameters  $(b, c, \alpha)$  of the LUT, and is manifestly rephasing invariant. We also note that the form of Eq.[\(23\)](#page-3-5) holds for both neutrino-mass-orderings. For the normal mass-ordering  $(m_1 < m_2 \ll m_3)$ ,  $\Delta$  and  $\epsilon$  are positive, while for the inverted mass-ordering  $(m_2 > m_1 \gg m_3)$ , they are both negative.

In the following, we analyze the accuracy of Eq.[\(23\)](#page-3-5) for practical applications. We first compute the probability from Eq.[\(23\)](#page-3-5) and compare it with the exact numerical result from solving the neutrino evolution equation [\(3\)](#page-1-0). We present this comparison in Fig.  $3(a)$  $3(a)$ -(b) for the on-going NO $\nu$ A experiment with baseline  $L = 810$  km. In plot-(a), the red dashed curves depict the prediction  $P_{\text{LUT}}$  of our LUT formula [\(23\)](#page-3-5), and the green curve stands for

the exact numerical result  $P_{\text{Exact}}$ . In Fig. [3\(](#page-4-0)b), we further present the difference  $\Delta P = P_{\text{LUT}} - P_{\text{Exact}}$  by red dashed curve.

For the comparison in Fig. [3,](#page-4-0) we further examine the approximate formula used by Particle Data Group (PDG) [\[5\]](#page-8-3)[\[19\]](#page-8-15)[\[21\]](#page-9-0),

<span id="page-4-1"></span>
$$
P_{\rm PDG}(\nu_{\mu} \to \nu_{e}) =
$$
  
\n
$$
\frac{1}{(1 - n_{E})^{2}} \sin^{2} \theta_{a} \sin^{2} 2\theta_{x} \sin^{2} [(1 - n_{E})\Delta]
$$
  
\n
$$
-\frac{\epsilon}{n_{E}(1 - n_{E})} \sin 2\theta_{s} \sin 2\theta_{a} \sin 2\theta_{x} \cos \theta_{x} \sin \delta
$$
  
\n
$$
\times \sin \Delta \sin(n_{E}\Delta) \sin[(1 - n_{E})\Delta]
$$
  
\n
$$
+\frac{\epsilon}{n_{E}(1 - n_{E})} \sin 2\theta_{s} \sin 2\theta_{a} \sin 2\theta_{x} \cos \theta_{x} \cos \delta
$$
  
\n
$$
\times \cos \Delta \sin(n_{E}\Delta) \sin[(1 - n_{E})\Delta]
$$
  
\n
$$
+\frac{\epsilon^{2}}{n_{E}^{2}} \sin^{2} 2\theta_{s} \cos^{2} \theta_{a} \sin^{2}(n_{E}\Delta),
$$
 (24)

where  $(\theta_s, \theta_a, \theta_x) \equiv (\theta_{12}, \theta_{23}, \theta_{13})$  and  $\delta$  is CP angle. Eq.[\(24\)](#page-4-1) is widely adopted by LBL experiments for data analysis, including the recent work of T2K [\[20\]](#page-8-16). (Some other approximate formulas using the conventional PMNS parametrization appeared in the literature  $[22]$ .) Eq. $(24)$  is much more complex than our LUT Eq. [\(23\)](#page-3-5). For comparison, we plot the probability  $P_{\text{PDG}}$ by blue dashed curves in Figs.  $3(a)$  $3(a)$ . We further depict the difference  $\Delta P = P_{PDG} - P_{Exact}$  (blue dashed curve) in Figs. [3\(](#page-4-0)b). For illustrating the applications of Eqs.[\(23\)](#page-3-5)- [\(24\)](#page-4-1) in Fig. [3,](#page-4-0) we have input central values of the current global fit [\[16\]](#page-8-12) for neutrino parameters under the normal mass-ordering. We have also made similar comparisons under the inverted mass-ordering.

Fig. [3](#page-4-0) demonstrates that for applications to LBL experiments (such as  $NO\nu A$  [\[14\]](#page-8-10)), our LUT formula [\(23\)](#page-3-5) is very accurate and its error is negligible for the current experimental precision. It shows that  $Eq.(23)$  $Eq.(23)$  is as precise as or better than the widely-used PDG Eq. $(24)$ . Eq. $(23)$  contains only 3 independent LUT parameters  $(b, c, \alpha)$ , and is manifestly rephasing-invariant. In contrast, Eq.[\(24\)](#page-4-1) depends on all 4 PMNS-parameters  $(\theta_s, \theta_a, \theta_x, \delta)$ .

Note that  $Eq.(23)$  $Eq.(23)$  is derived from our independent new LUT approach and stands on its own, even though Fig.  $3(a)$  $3(a)$  shows that Eqs.[\(23\)](#page-3-5) and [\(24\)](#page-4-1) are in main agreement. We stress that  $Eqs.(23)$  $Eqs.(23)$  and  $(24)$  have their own advantages via two independent formulations of  $\nu$ oscillation; they are complementary for studying different aspects of neutrino oscillations. For current illustrations, we mainly consider the important on-going experiment NO $\nu$ A ( $L = 810 \text{ km}$ ) [\[14\]](#page-8-10) as an example. We have also reached similar conclusions by analyzing other LBL experiments MINOS  $(L = 735 \text{ km})$  [\[13\]](#page-8-9) and T2K  $(L = 295 \text{ km})$  [\[20\]](#page-8-16), as well as the planned future experiment DUNE  $(L = 1300 \text{ km})$  [\[15\]](#page-8-11). For further justifications of our LUT matter formula [\(23\)](#page-3-5), we will

<span id="page-4-0"></span>Figure 3: Comparison of the approximate analytical oscillation formulae [\(23\)](#page-3-5) and [\(24\)](#page-4-1) with the exact numerical result (green curve) for the case of NO $\nu$ A experiment ( $L = 810 \text{ km}$ ).  $Eq.(23)$  $Eq.(23)$  is plotted in red curve, and  $Eq.(24)$  $Eq.(24)$  is in blue curve. Plot-(a) shows that both Eqs.[\(23\)](#page-3-5)-[\(24\)](#page-4-1) are fairly accurate and their errors are negligible for practical use. Plot-(b) depicts the differences  $\Delta P = P_{\text{LUT}} - P$  (red curve) and  $\Delta P = P_{PDG} - P$  (blue curve), showing that our LUT formula  $(23)$  is as accurate as Eq. $(24)$ .

present explicit analyses for both T2K and DUNE experiments in Appendix [B,](#page-7-1) covering a wide baseline range of  $L = 295 - 1300$  km.

In passing, we note that in principle, both formulae [\(23\)](#page-3-5) and [\(24\)](#page-4-1) require  $\epsilon \ll n_E$ , which corresponds to a lower bound on neutrino energy,

<span id="page-4-2"></span>
$$
E \ge 0.34 \text{GeV} \left( \frac{\Delta m_{21}^2}{7.6 \times 10^{-5} \text{eV}^2} \frac{1.4 \text{cm}^{-3} N_A}{N_e} \right), \tag{25}
$$

as given in Ref. [\[19\]](#page-8-15) and updated by PDG [\[5\]](#page-8-3) (cf. the note below Eq.(14.76) in Ref. [\[5\]](#page-8-3)). For NO $\nu$ A experiment, the selected neutrino energy range is  $1.5 \,\text{GeV} \leq E \leq 2.7 \,\text{GeV}$ [\[14\]](#page-8-10), which well obeys the lower bound [\(25\)](#page-4-2). For the case of T2K experiment, it has neutrino energy range,  $0.1 \,\text{GeV} \leq E \leq 1.2 \,\text{GeV}$  [\[12\]](#page-8-8). So we may concern the validity of our formula for  $E = (0.1 - 0.34)$  GeV. Our derivation in Sec. [III](#page-2-0) has made  $\epsilon$  expansion, which requires  $\epsilon \ll n_E$ . We note that the approximate Eq.[\(22a\)](#page-3-4) for  $b_m$  is singular in the limit  $E \to 0$  (which causes  $n_E \to 0$ ). But our Eq.[\(23\)](#page-3-5) is free from this singularity

because its  $n_E = 0$  poles are actually canceled in the limit  $n_E \rightarrow 0$ . So, Eq.[\(23\)](#page-3-5) still holds well around this limit. Also, a singularity  $n_E = 1$  appears in Eq.[\(22a\)](#page-3-4) for  $c_m$ . Again, it is fully canceled in Eq.[\(23\)](#page-3-5), and is harmless. Note that the PDG Eq.[\(24\)](#page-4-1) is also singularityfree in the limit  $n_E \to 1$ , or,  $n_E \to 0$  [even though the perturbative expansion requires  $\epsilon \ll n_E$  and thus the bound [\(25\)](#page-4-2)]. But exact numerical calculations have verified that Eq.[\(24\)](#page-4-1) remains fairly accurate below the bound [\(25\)](#page-4-2). Hence, Eq.[\(24\)](#page-4-1) was safely adopted by T2K analysis [\[12\]](#page-8-8). Ref. [\[23\]](#page-9-2) recently explained why Eq.[\(24\)](#page-4-1) still holds at energies below the bound [\(25\)](#page-4-2). For our LUT Eq.[\(23\)](#page-3-5), we have demonstrated its validity for various oscillation experiments by comparing it with the exact numerical results in Fig. [3](#page-4-0) and in Appendix [B.](#page-7-1) We also expect similar reasons to explain the high numerical precision of our LUT Eq.[\(23\)](#page-3-5), and will study the detail of this issue elsewhere.

#### <span id="page-5-1"></span>V. Conclusions

Leptonic unitarity triangle (LUT) provides fundamental means to geometrically describe CP violation in neutrino oscillations. In this work, we presented a new unified geometrical formulation for connecting the LUT to neutrino oscillations in vacuum and in matter. We demonstrated that the dependence of the vacuum oscillation probability on the PMNS mixing matrix can be fully reformulated in terms of only 3 independent geometrical parameters of the corresponding LUT, which are rephasing invariant. We further constructed the geometrical formulation of oscillations in matter, and derived a very compact and accurate new oscillation formula.

In Sec.[II,](#page-0-0) we proposed a new geometrical LUT formulation of the dynamical 3-neutrino oscillations. We proved that the vacuum oscillation probability can be derived by directly computing the distance of two points circling around a vertex of the LUT, as shown in Fig. [2](#page-1-2) and given in Eqs. $(9)(12)$  $(9)(12)$ . The formula  $(12)$  manifestly depends on only 3 independent parameters of the corresponding LUT, and takes a much simpler form than Eqs.[\(16\)](#page-2-6)-[\(17\)](#page-2-7) which we derived before  $|6|$ . For neutrino oscillations in matter, we constructed the corresponding Effective LUT (ELUT) in Sec.[III,](#page-2-0) which is a deformed LUT by including matter effects. Eqs. $(21)-(22)$  $(21)-(22)$  $(21)-(22)$ presented a new geometrical oscillation formula including matter effects. Note that Eqs.[\(12\)](#page-2-1) and [\(21\)](#page-3-2) exhibit LO+NLO+NNLO structure, but hold exactly without approximation. To analytically connect the ELUT parameters in Eq. $(21)$  to the vacuum LUT parameters, we deduced new relations [\(22a\)](#page-3-4)-[\(22b\)](#page-3-4) under proper expansions, as shown in Appendix [A.](#page-5-0) With these, we further derived a very compact analytical formula [\(23\)](#page-3-5) in Sec.[IV.](#page-3-0) We demonstrated that Eq. [\(23\)](#page-3-5) has high accuracy for applications to long baseline experiments, such as  $NQ\nu A$ (Fig. [3\)](#page-4-0) and MINOS, as well as T2K and DUNE (cf. Figs. [4-](#page-8-17)[5](#page-8-18) in Appendix [B\)](#page-7-1). We showed that the numerical precision of our LUT formula [\(23\)](#page-3-5) is as good as (or better than) the widely used PDG Eq.[\(24\)](#page-4-1) [\[5\]](#page-8-3), for the long baseline oscillation experiments T2K, MINOS, NO $\nu$ A, and DUNE.

#### <span id="page-5-0"></span>Appendix A: Derivation of Matter Formula (22)

In this Appendix, we present the highly nontrivial derivation of the matter formula [\(22\)](#page-3-3), shown at the end of Sec. III in the main text.

Inspecting the effective Hamiltonian  $H = H_0 + H_i$  in Eqs.[\(4\)](#page-1-6) and  $(18)$ , we can separate out a diagonal term  $(m_1^2/2E)\mathbb{I}$  and express H as follows,

<span id="page-5-4"></span>
$$
H = \frac{m_1^2}{2E} \mathbb{I} + \frac{\Delta m_{31}^2}{2E} U \mathbb{K} U^{\dagger}, \tag{A1}
$$

where  $\mathbb{I}$  is the  $3 \times 3$  unit matrix. The dimensionless matrix K takes the following convenient form, and needs to be diagonalized,

<span id="page-5-3"></span>
$$
\mathbb{K} = \begin{pmatrix} 0 \\ \epsilon \\ 1 \end{pmatrix} + n_E u_e u_e^{\dagger}, \tag{A2}
$$

where  $u_e^{\dagger}$  is the first row of U. To be concrete, we parametrize U as

<span id="page-5-2"></span>
$$
U = \begin{pmatrix} c_s c_x & s_s c_x & s_x \\ -e^{-i\delta} s_s c_a - c_s s_a s_x & e^{-i\delta} c_s c_a - s_s s_a s_x & s_a c_x \\ e^{-i\delta} s_s s_a - c_s c_a s_x & -e^{-i\delta} c_s s_a - s_s c_a s_x & c_a c_x \end{pmatrix}, \quad (A3)
$$

where we have used notations,  $(s_j, c_j) = (\sin \theta_j, \cos \theta_j)$ , and  $(\theta_s, \theta_a, \theta_x) = (\theta_{12}, \theta_{23}, \theta_{13})$ . Thus, we have

$$
u_e = (c_s c_x, \, s_s c_x, \, s_x)^T,\tag{A4}
$$

where  $u_e$  is real under this convention, and thus  $u_e^{\dagger} =$  $u_e^T$ . Hence, we are actually going to diagonalize a real matrix  $K$ . The final result of computing the ELUT does not depend on the parametrization of U. Note that  $Eq. (A3)$  $Eq. (A3)$  can be obtained from the standard parametrization of PMNS matrix  $U<sub>S</sub>$  [\[5\]](#page-8-3) via simple rephasing,

$$
U = \text{diag}(1, e^{-i\delta}, e^{-i\delta}) U_S \text{diag}(1, 1, e^{i\delta}), \quad (A5)
$$

where  $U<sub>S</sub>$  is given by [\[5\]](#page-8-3),

$$
U_{S} = \begin{pmatrix} c_{s}c_{x} & s_{s}c_{x} & e^{-i\delta}s_{x} \\ -s_{s}c_{a}-e^{i\delta}c_{s}s_{a}s_{x} & c_{s}c_{a}-e^{i\delta}s_{s}s_{a}s_{x} & s_{a}c_{x} \\ s_{s}s_{a}-e^{i\delta}c_{s}c_{a}s_{x} & -c_{s}s_{a}-e^{i\delta}s_{s}c_{a}s_{x} & c_{a}c_{x} \end{pmatrix}.
$$
 (A6)

Using the following 1-2 rotation

$$
O_{12} = \begin{pmatrix} c_s & -s_s & 0 \\ s_s & c_s & 0 \\ 0 & 0 & 1 \end{pmatrix}, \tag{A7}
$$

we can rotate  $u_e$  into a vector containing only two nonzero elements,

<span id="page-6-2"></span>
$$
u_e^{\dagger} O_{12} = u_e^T O_{12} = (c_x, 0, s_x). \tag{A8}
$$

Then, we find that  $n_E u_e u_e^{\dagger}$  in Eq.[\(A2\)](#page-5-3) will be rotated into a matrix having only two off-diagonal elements,

$$
n_E O_{12}^T (u_e u_e^{\dagger}) O_{12} = n_E \begin{pmatrix} c_x^2 & 0 & s_x c_x \\ 0 & 0 & 0 \\ s_x c_x & 0 & s_x^2 \end{pmatrix} .
$$
 (A9)

For  $\epsilon = 0$ , after the 1-2 rotation  $O_{12}$ , Eq.[\(A2\)](#page-5-3) will be rotated to

<span id="page-6-0"></span>
$$
O_{12}^T \mathbb{K}_0 O_{12} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} + n_E \begin{pmatrix} c_x^2 & 0 & s_x c_x \\ 0 & 0 & 0 \\ s_x c_x & 0 & s_x^2 \end{pmatrix}, \quad (A10)
$$

where  $\mathbb{K}_0$  is defined as,  $\mathbb{K}_0 = \mathbb{K}|_{\epsilon=0}$ . Thus, to diagonalize the matrix in Eq. [\(A10\)](#page-6-0), we just need an 1-3 rotation,

<span id="page-6-1"></span>
$$
O_{13} = \begin{pmatrix} c_{\theta} & 0 & s_{\theta} \\ 0 & 1 & 0 \\ -s_{\theta} & 0 & c_{\theta} \end{pmatrix},
$$
 (A11)

where  $(s_{\theta}, c_{\theta}) = (\sin \theta, \cos \theta)$ . Under the rotation [\(A11\)](#page-6-1),  $Eq.(A8)$  $Eq.(A8)$  is transformed to

$$
u_e^{\dagger} O_{12} O_{13} = (c_y, 0, s_y) , \qquad (A12)
$$

where  $(s_y, c_y) = (\sin \theta_y, \cos \theta_y)$ , and  $\theta_y = \theta + \theta_x$ . Then, the matrix [\(A10\)](#page-6-0) is rotated to

<span id="page-6-3"></span>
$$
O_{13}^T O_{12}^T \mathbb{K}_0 O_{12} O_{13}
$$
  
= 
$$
\begin{pmatrix} s_\theta^2 & 0 & -s_\theta c_\theta \\ 0 & 0 & 0 \\ -s_\theta c_\theta & 0 & c_\theta^2 \end{pmatrix} + n_E \begin{pmatrix} c_y^2 & 0 & s_y c_y \\ 0 & 0 & 0 \\ s_y c_y & 0 & s_y^2 \end{pmatrix}
$$
  
= 
$$
\begin{pmatrix} \lambda_- & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \lambda_+ \end{pmatrix},
$$
(A13)

where we have defined,

<span id="page-6-9"></span>
$$
\lambda_{-} = s_{\theta}^{2} + n_{E} c_{y}^{2}, \qquad \lambda_{+} = c_{\theta}^{2} + n_{E} s_{y}^{2}. \tag{A14}
$$

In the second equality of Eq.[\(A13\)](#page-6-3), we have imposed the following condition on the  $(1,3)$  and  $(3,1)$  elements to ensure full diagonalization,

$$
n_E s_y c_y - s_\theta c_\theta = 0. \tag{A15}
$$

This leads to

<span id="page-6-5"></span>
$$
\sin(2\theta) = n_E \sin(2\theta_y). \tag{A16}
$$

Given the relation  $\theta_y = \theta + \theta_x$ , we can solve  $\theta$  as a function of  $\theta_x$ ,

<span id="page-6-6"></span>
$$
\tan 2\theta = \frac{n_E \sin(2\theta_x)}{1 - n_E \cos(2\theta_x)}.
$$
 (A17)

Hence, we have determined the 1-3 rotation and diagonalized the matrix  $\mathbb K$  under  $\epsilon = 0$  limit. The diagonalization matrix is  $O_{12}O_{13}$ , and the effective mixing matrix in this case corresponds to  $\,{\cal U}_{m0}\,\equiv\,{\cal U}_m\vert_{\epsilon=0}\,,\,$  as given by

<span id="page-6-4"></span>
$$
U_{m0} = UO_{12}O_{13} = \begin{pmatrix} c_y & 0 & s_y \\ -s_y s_a & c_a e^{-i\delta} & c_y s_a \\ -s_y c_a & -s_a e^{-i\delta} & c_y c_a \end{pmatrix}.
$$
 (A18)

Hence, when  $\epsilon = 0$ , the effective unitarity triangle ex-tracted from Eq. [\(A18\)](#page-6-4) is actually a line for  $\nu_e - \nu_\mu$  or  $\nu_e - \nu_\tau$  oscillations, since in either case the length of the b side vanishes,

$$
b_{m0} = 0.\t\t(A19)
$$

The other two sides of this LUT have the same length,

<span id="page-6-7"></span>
$$
a_{m0} = c_{m0} = \frac{c}{\sqrt{(1 - n_E)^2 + 4n_E s_x^2}},
$$
 (A20)

where  $c = s_x c_x s_a$  (or,  $c = s_x c_x c_a$ ) is the length of c side of the vacuum LUT for  $\nu_e - \nu_\mu$  (or,  $\nu_e - \nu_\tau$ ) oscillations. We have made use of Eqs. $(A16)$ - $(A17)$  for deriving the formula [\(A20\)](#page-6-7).

Next, we compute the corrections from nonzero  $\epsilon$ . For  $\epsilon \neq 0$ , we can split the matrix K in Eq.[\(A2\)](#page-5-3) as follows,

$$
\mathbb{K} \equiv \mathbb{K}_0 + \mathbb{K}_{\epsilon} \,, \tag{A21}
$$

where

$$
\mathbb{K}_0 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} + n_E u_e u_e^T, \qquad \mathbb{K}_\epsilon = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}. \tag{A22}
$$

Then, under the rotation  $O_{12}O_{13}$ , the matrix  $\mathbb{K}_{\epsilon}$  transforms as

$$
O_{13}^T O_{12}^T \mathbb{K}_{\epsilon} O_{12} O_{13} = \epsilon \begin{pmatrix} s_s^2 & s_s c_s & 0 \\ s_s c_s & c_s^2 & 0 \\ 0 & 0 & 0 \end{pmatrix} + \mathcal{O}(10^{-3}),
$$
\n(A23)

where the corrections due to  $O_{13}$  rotation are suppressed by  $\epsilon \theta_{13} = \mathcal{O}(10^{-3})$ , and are negligible in the final result. Hence, under the rotations  $O_{12}O_{13}$ , we have the matrix K transform as

<span id="page-6-8"></span>
$$
\mathbb{K} \to \begin{pmatrix} \lambda_0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \lambda_+ \end{pmatrix} + \epsilon \begin{pmatrix} s_s^2 & s_s c_s & 0 \\ s_s c_s & c_s^2 & 0 \\ 0 & 0 & 0 \end{pmatrix} + \mathcal{O}(10^{-3}). \quad \text{(A24)}
$$

We can further diagonalize the right-hand-side of Eq.[\(A24\)](#page-6-8) by a rotation  $O'_{12}$ ,

$$
O'_{12} = \begin{pmatrix} c_r & -s_r & 0 \\ s_r & c_r & 0 \\ 0 & 0 & 1 \end{pmatrix}, \tag{A25}
$$

where  $(s_r, c_r) = (\sin \theta_r, \cos \theta_r)$ . Thus, we can determine the angle  $\theta_r$  as follows,

<span id="page-7-3"></span>
$$
\tan 2\theta_r = \frac{\epsilon \sin(2\theta_s)}{\lambda_- - \epsilon \cos(2\theta_s)}.
$$
 (A26)

With these, we combine the above rotation  $O'_{12}$  with  $U_{m0}$  in Eq.[\(A18\)](#page-6-4), and deduce the following rotation for full diagonalization,

<span id="page-7-2"></span>
$$
U_m = U_{m0}O'_{12}
$$
\n
$$
= \begin{pmatrix} c_y c_r & -s_r c_y & s_y \\ s_r c_a e^{-i\delta} - c_r s_a s_y & c_r c_a e^{-i\delta} + s_r s_y s_a & c_y s_a \\ \times & \times & \times \end{pmatrix},
$$
\n(A27)

where  $\times$  stands for the elements irrelevant to our current concern. For the  $\nu_e - \nu_\mu$  LUT, using Eqs.[\(A27\)](#page-7-2) and [\(A26\)](#page-7-3), we derive

$$
b_m = s_r c_y \left| c_r c_a e^{-i\delta} + s_r s_y s_a \right|
$$
  
= 
$$
\frac{\epsilon s_{2s} c_a c_y}{2\sqrt{(\lambda - \epsilon c_{2s})^2 + \epsilon^2 s_{2s}^2}} [1 + \mathcal{O}(\epsilon \theta_x)], \quad \text{(A28)}
$$

where  $(s_{2s}, c_{2s}) = (\sin 2\theta_s, \cos 2\theta_s)$ . This gives a small but non-zero length for the b-side of the deformed effective unitarity triangle,

$$
b_m \simeq \frac{\epsilon}{\lambda_-} b. \tag{A29}
$$

The length of c-side is not changed from the leading order result because the last column of  $U_m$  equals that of  $U_{m0}$ ,

$$
c_m \simeq c_{m0} \,, \tag{A30}
$$

with  $c_{m0}$  given by Eq.[\(A20\)](#page-6-7). Since the current global fits of neutrino data [\[16\]](#page-8-12)[\[17\]](#page-8-13) restrict the  $3\sigma$  range of  $\theta_{13} \equiv$  $\theta_x \simeq 0.137 - 0.158 = \mathcal{O}(0.1) \ll 1$ , we see that  $s_y^2 \sim$  $s_{\theta}^2 \sim s_x^2 = \mathcal{O}(10^{-2})$  are fairly small. This applies to Eqs. $(A20)$  and  $(A14)$ . Hence, we deduce the approximate relations,  $b_m \simeq \epsilon b/n_E$  and  $c_m \simeq c/(1-n_E)$ , which lead to Eq. [\(22a\)](#page-3-4).

From the definition of  $\alpha$  in Eq.(2b), and using the formulas [\(A3\)](#page-5-2) and [\(A27\)](#page-7-2), we have  $\alpha = -\arg(-U_{\mu 2})$ and  $\alpha_m = -\arg((U_m)_{\mu 2})$ , where the expression of  $\alpha_m$ does not have a "−" sign in front of  $(U_m)_{\mu 2}$  because it is canceled by the negative sign in  $(U_m)_{e2}$ . Ignoring  $s_x, s_y = \mathcal{O}(0.1)$ , we have  $\arg(U_{\mu 2}) \simeq \arg((U_m)_{\mu 2})$ , and thus  $\alpha_m \simeq \alpha \pm \pi$ , which reproduces the third relation of Eq.[\(22a\)](#page-3-4). Hence, the final ELUT is approximately given by Eq. $(22a)$ . To derive Eq. $(22b)$ , we note that at  $\mathcal{O}(\epsilon^0)$ , the eigenvalues of the matrix K in Eq.[\(A24\)](#page-6-8) are

 $(\lambda_-, 0, \lambda_+)$ . Accordingly, the effective Hamiltonian [\(A1\)](#page-5-4) has three eigenvalues,

$$
\left(\frac{m_1^2 + \Delta m_{31}^2 \lambda}{2E}, \frac{m_1^2}{2E}, \frac{m_1^2 + \Delta m_{31}^2 \lambda_+}{2E}\right), \quad \text{(A31)}
$$

which should equal the corresponding eigenvalues  $(\tilde{m}_1^2, \tilde{m}_2^2, \tilde{m}_3^2)/(2E)$  as defined in Eq.[\(20\)](#page-3-1). Hence, we deduce the effective mass-squared differences at  $\mathcal{O}(\epsilon^0)$ ,

$$
\Delta \tilde{m}_{31}^2 \simeq (\lambda_+ - \lambda_-) \Delta m_{31}^2,
$$
  

$$
\Delta \tilde{m}_{21}^2 \simeq (-\lambda_-) \Delta m_{31}^2.
$$
 (A32)

Using this and  $Eq.(A14)$  $Eq.(A14)$ , we derive the approximate formulas,  $\epsilon_m \simeq -n_E/(1 - n_E)$  and  $\Delta_m \simeq (1 - n_E)\Delta$ , by dropping small  $\mathcal{O}(s_x^2)$  terms. This just reproduces Eq.[\(22b\)](#page-3-4) in the main text.

In summary, we have proven the approximate formulas  $(22a)-(22b)$  $(22a)-(22b)$  $(22a)-(22b)$  in the main text.

#### <span id="page-7-1"></span>Appendix B: Further Tests of Matter Formula (23)

In this Appendix, we further present two important tests of our new LUT formula [\(23\)](#page-3-5) by using the long baseline oscillation experiments T2K [\[20\]](#page-8-16) and DUNE [\[15\]](#page-8-11).

The baselines of the T2K and DUNE experiments are  $L = 295$  km and  $L = 1300$  km, respectively. We present the predictions of our Eq.[\(23\)](#page-3-5) for T2K experiment in Fig.  $4(a)$  $4(a)$  and for DUNE experiment in Fig.  $5(a)$  $5(a)$ , by the red dashed curves. Then, we compare them with the exact numerical results (green solid curves) in each plot. For comparison, we further show the results of the conventional formula  $(24)$  (used by the PDG [\[5\]](#page-8-3)) in the blue dashed curves. We see that in each case, the three curves agree with each other to high precision, similar to our findings in Fig. [3](#page-4-0) for  $NO\nu A$  experiment.

In Fig.  $4(b)$  $4(b)$  and Fig.  $5(b)$  $5(b)$ , we further compare the differences,  $\Delta P = P_{\text{LUT}} - P$  (red dashed curves) and  $\Delta P = P_{\rm PDG}-P$  (blue dashed curves). Again, these comparisons explicitly demonstrate that our LUT formula [\(23\)](#page-3-5) is as accurate as (or better than) the conventional PDG formula [\(24\)](#page-4-1).

## Acknowledgments:

We are grateful to Sheldon Glashow, John Ellis, Manfred Lindner, and Jose Valle for valuable discussions. We thank Eligio Lisi for valuable discussions during and after his visit to Tsinghua HEP Center. We thank Yu-Chen Wang and Zhe Wang for useful discussions. This research was supported in part by the National NSF of China (under grants 11275101, 11135003, 11675086).
