# COMPARING DIAGONALS ON THE ASSOCIAHEDRA

SAMSON SANEBLIDZE AND RONALD UMBLE

ABSTRACT. We prove that the formula for the diagonal approximation  $\Delta_K$  on J. Stasheff's *n*-dimensional associahedron  $K_{n+2}$  derived by the current authors in [7] agrees with the "magical formula" for the diagonal approximation  $\Delta'_K$  derived by Markl and Shnider in [5], by J.-L. Loday in [4], and more recently by Masuda, Thomas, Tonks, and Vallette in [6].

Dedicated to the memory of Jean-Louis Loday

#### 1. INTRODUCTION

Recently there has been renewed interest in explicit combinatorial diagonal approximations on J. Stasheff's *n*-dimensional associahedron  $K_{n+2}$  [8]. Markl and Shnider (M-S) in [5], J.-L. Loday in [4], and more recently Masuda, Thomas, Tonks, and Vallette (MTTV) in [6] constructed a diagonal  $\Delta'_K$  on  $K_{n+2}$  whose components are "matching pairs" of faces, which in the words of Jean-Louis Loday, are "pairs of cells of matching dimensions and comparable under the Tamari order." By definition, every component of the combinatorial diagonal  $\Delta_K$  on  $K_{n+2}$  constructed by the current authors (S-U) in [7] is a matching pair. In this paper we prove that every matching pair is a component of  $\Delta_K$ . Thus the S-U formula for  $\Delta_K$  and the "magical formula" for  $\Delta'_K$  agree (see Definitions 2.4 and 3.1).

Historically, S-U were the first to derive a cellular combinatorial/differential graded formula for  $\Delta_K$ , M-S were the first to prove the magical formula for  $\Delta'_K$ , and MTTV were the first to construct a point-set topological diagonal map, which descends to the magical formula at the cellular level.

Using the geometric methods of MTTV, Laplante-Anfossi created a general framework for studying diagonals on any polytope in [3]. In this framework, a choice of diagonal on the *n*-dimensional permutahedron  $P_{n+1}$  is given by a choice of chambers in its fundamental hyperplane arrangement ([3], Def. 1.18). While the specific diagonal  $\Delta'_P$  on  $P_{n+1}$  studied in [3] differs from the S-U diagonal  $\Delta_P$ , the diagonal  $\Delta'_K$  on  $K_{n+2}$  induced by  $\Delta'_P$  agrees with  $\Delta_K$ .

Acknowledgments. We wish to thank Bruno Vallette for sharing his perspective on the history of combinatorial diagonals on  $K_n$ , and Guillaume Laplante-Anfossi and our anonymous referee for their helpful editorial suggestions.

### 2. Diagonals Induced by $\Delta_P$

Let  $S_n$  be the symmetric group on the finite set  $\underline{n} = \{1, 2, \ldots, n\}$ . The permutahedron  $P_n$  is the convex hull of n! vertices  $\{(\sigma(1), \ldots, \sigma(n)) : \sigma \in S_n\} \subset \mathbb{R}^n$ . As a cellular complex,  $P_n$  is an (n-1)-dimensional convex polytope whose (n-p)-faces are indexed by (ordered) partitions  $A_1 | \cdots | A_p$  of  $\underline{n}$ ,  $1 \leq p \leq n$ . Denoting the set of ordered partitions of  $\underline{n}$  by P(n), the faces of  $P_n$  are identified with elements of P(n) in the standard way.

Let X be an n-dimensional polytope that admits a (surjective) cellular projection map  $p: P_{n+1} \to X$  and a realization as a subdivision of the n-cube  $I^n$ , i.e., for  $0 \le k \le n$ , each k-cell (k-subcube) of  $I^n$  is a union of k-cells of X, any two of which intersect along their boundaries.

For example,  $X = P_n$  can be realized as a subdivision of  $I^{n-1}$  inductively as follows: Identify  $P_1$  with  $1 \in P(1)$ . If  $P_{n-1}$  has been constructed and  $a = A_1 | \cdots | A_p \in P(n-1)$  is a face, let  $a_0 = 0$ ,  $a_j = \# (A_{p-j+1} \cup \cdots \cup A_p)$  for 0 < j < p,  $a_p = \infty$ , and define  $\frac{1}{2^{\infty}} := 0$ . Let  $I(a) := I_1 \cup I_2 \cup \cdots \cup I_p$ , where  $I_j := [1 - \frac{1}{2^{a_{j-1}}}, 1 - \frac{1}{2^{a_j}}]$ ; then  $P_n = \bigcup_{a \in P(n-1)} a \times I(a)$ , where the identification of faces with partitions is given by

Face of $a \times I(a)$	<b>Partition in</b> $P(n)$	
a  imes 0	$A_1 \cdots A_p n$	
$a \times (I_j \cap I_{j+1})$	$A_1 \cdots A_{p-j} n A_{p-j+1} \cdots A_p,$	$1 \leq j \leq p-1$
$a \times 1$	$n A_1 \cdots A_p,$	
$a \times I_j$	$A_1 \cdots A_{p-j+1}\cup n \cdots A_p,$	$1 \leq j \leq p$

(see Figures 1 and 2). We refer to a vertex common to  $P_n$  and  $I^{n-1}$  as a *cubical* vertex. Thus a is a cubical vertex of  $P_n$  if and only if a|n and n|a are cubical vertices of  $P_{n+1}$ . Indeed, a cubical vertex has the form  $a = a_1|\cdots|a_{i-1}|1|a_{i+1}|\cdots|a_n$ , where  $a_1 > \cdots > a_{i-1}$  and  $a_{i+1} < \cdots < a_n$ .

We begin with a review of the diagonal  $\Delta_P$  and the diagonal  $\Delta_X$  induced by the projection p; then  $\Delta_K$  is obtained by setting  $X = K_{n+2}$ . Whereas the vertices of  $P_{n+1}$  are identified with the permutations in  $S_{n+1}$ , the weak order on  $S_{n+1}$  given by  $\cdots |x_i|x_{i+1}| \cdots < \cdots |x_{i+1}|x_i| \cdots$  if  $x_i < x_{i+1}$  extends to a partial order (p-o) and the associated Hasse diagram orients the 1-skeleton of  $P_{n+1}$  [1]. Denote the minimal and maximal vertices of a face e of  $P_{n+1}$  by min e and max e, respectively, and define  $e \leq e'$  if there exists an oriented edge-path in  $P_{n+1}$  from max e to min e'. Then p induces a p-o on the cells of X. For example, when the faces of  $P_{n+1}$  are indexed by planar leveled trees (PLTs) with n+2 leaves (without levels), Tonks' projection  $p = \theta$  given by forgetting levels [9] induces the *Tamari order* on the faces  $\{\theta(T_i)\}$  of  $K_{n+2}$  given by  $\theta(T_i) \leq \theta(T_j)$  if  $T_i \leq T_j$ . In particular, the vertices of  $K_{n+1}$  form a subset of the vertices  $P_n$  and the Tamari order restricted to this subset agrees with the weak order.

Let e be a cell of X and let |e| denote its dimension. A k-subdivision cube of e is a set of faces of e whose union is a k-subcube of  $I^n$  for some  $k \leq n$ . For example, when e is the top dimensional cell of  $P_4$ , the facets in  $\{2|134, 24|13\}$  and  $\{2|134, 24|13, 23|14, 234|1\}$  form 2-subdivision cubes of e, but any three in the latter do not (see Figure 2). Denote the set of vertices of e by  $\mathcal{V}_e$  (when e = X we suppress

the subscript e). Given a vertex  $v \in \mathcal{V}_e$ , let  $I_{v,1}^{k_1}$  and  $I_{v,2}^{k_2}$  be  $k_i$ -subdivision cubes of e such that max  $I_{v,1}^{k_1} = \min I_{v,2}^{k_2} = v$  and  $k_1 + k_2 = |e|$ ; then  $\left(I_{v,1}^{k_1}, I_{v,2}^{k_2}\right)$  is a pair of  $(k_1, k_2)$ -subdivision cubes of e. Denote the set of all such pairs by  $e_v$  and let  $(\mathbf{I}_{v,1}^{k_1}, \mathbf{I}_{v,2}^{k_2})_e$  denote its unique maximal element; then  $\left(I_{v,3}^{k_3}, I_{v,4}^{k_4}\right) \subseteq (\mathbf{I}_{v,1}^{k_1}, \mathbf{I}_{v,2}^{k_2})_e$ for all  $(I_{v,3}^{k_3}, I_{v,4}^{k_4}) \in e_v$ . For example, when e is the top dimensional cell of  $P_4$ and v = 4|2|3|1, we have  $(\mathbf{I}_{v,1}^2, \mathbf{I}_{v,2}^1)_e = (\{2|134, 24|13\}, \{4|23|1\})$ . For an explicit description of  $\left(\mathbf{I}_{v,1}^{k_1}, \mathbf{I}_{v,2}^{k_2}\right)_e$  when  $e \subseteq P_n$  see (2.3) below.

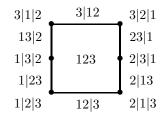

Figure 1:  $P_3$  as a subdivision of  $P_2 \times I$ .

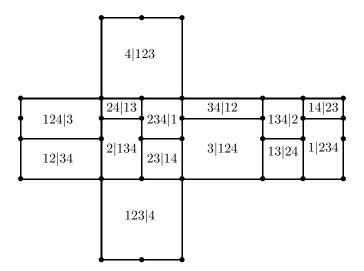

Figure 2: The facets of  $P_4$  as a subdivision of  $I^3$ .

If in addition, the cellular projection  $p: P_{n+1} \to X$  preserves maximal pairs of  $(k_1, k_2)$ -subdivision cubes, i.e., for every cell e of  $P_{n+1}$  we have

$$p\left(\mathbf{I}_{v,1}^{k_{1}},\mathbf{I}_{v,2}^{k_{2}}\right)_{e} = \left(\mathbf{I}_{p(v),1}^{k_{1}},\mathbf{I}_{p(v),2}^{k_{2}}\right)_{p(e)},$$

the components of the induced diagonal  $\Delta_X$  on a cell  $f \subseteq X$  form the set of product cells

(2.1) 
$$\Delta_X(f) := \bigcup_{\substack{(e^{k_1}, e^{k_2}) \in \left(\mathbf{I}_{v,1}^{k_1}, \mathbf{I}_{v,2}^{k_2}\right)_f \\ v \in \mathcal{V}_f}} \{e^{k_1} \times e^{k_2}\}.$$

In particular,  $p = \theta$  preserves maximal pairs of  $(k_1, k_2)$ -subdivision cubes and  $\Delta_K(e)$  is given by setting  $X = K_{n+2}$  (see (2.4) below). Note that  $(e^{k_1}, e^{k_2}) \in (\mathbf{I}_{v,1}^{k_1}, \mathbf{I}_{v,2}^{k_2})_X$  implies  $e^{k_1} \leq e^{k_2}$ . Thus  $e^{k_1} \times e^{k_2}$  is a "matching pair" in the sense of MTTV (see Definition 2). Furthermore, since f = p(e) for some

$$e = P_{n_1} \times \cdots \times P_{n_s}$$
 and  $p(e) = p(P_{n_1}) \times \cdots \times p(P_{n_s})$ ,

the diagonal  $\Delta_X(f)$  is automatically the comultiplicative extension of its values on the factors of f, i.e.,

$$\Delta_X(f) = \Delta_X(p(P_{n_1})) \times \cdots \times \Delta_X(p(P_{n_s})).$$

The subset  $\mathcal{V}_e \subseteq S_n$  determines the components of  $\Delta_P(e)$  in the following way: Let  $\sigma = x_1 | \cdots | x_n \in \mathcal{V}_e$ . Reading  $\sigma$  from left-to-right and from right-to-left, construct the partitions  $\overleftarrow{\sigma}_1 | \cdots | \overleftarrow{\sigma}_p$  and  $\overrightarrow{\sigma}_q | \cdots | \overrightarrow{\sigma}_1$  of maximal decreasing subsets and form the *Strong Complementary Pair* (SCP)

$$a_{\sigma} \times b_{\sigma} := \overleftarrow{\sigma}_1 | \cdots | \overleftarrow{\sigma}_p \times \overrightarrow{\sigma}_q | \cdots | \overrightarrow{\sigma}_1 \in P(n) \times P(n)$$

Then

$$\sigma = \max a_{\sigma} = \min b_{\sigma}, \ \min \overleftarrow{\sigma}_{j} < \max \overleftarrow{\sigma}_{j+1} \text{ for all } j < p, \text{ and} \\ \min \overrightarrow{\sigma}_{i} < \max \overrightarrow{\sigma}_{i+1} \text{ for all } i < q.$$

Thus, for  $\sigma = 2|1|3|5|4$  we have  $\overleftarrow{\sigma}_1|\overleftarrow{\sigma}_2|\overleftarrow{\sigma}_3 = 21|3|54$  and  $\overrightarrow{\sigma}_3|\overrightarrow{\sigma}_2|\overrightarrow{\sigma}_1 = 2|135|4$  so that  $a_{\sigma} \times b_{\sigma} = 21|3|54 \times 2|135|4$ .

Let  $a = A_1 | \cdots | A_p \in P(n)$ . For  $1 \le j < p$ , let  $M_j \subseteq (A_j \setminus \{\min A_j\})$  such that  $\min M_j > \max A_{j+1}$  when  $M_j \ne \emptyset$ . Define the right-shift  $M_j$  action

$$R_{M_j}(a) := \begin{cases} A_1 | \cdots | A_j \smallsetminus M_j | A_{j+1} \cup M_j | \cdots | A_k, & M_j \neq \emptyset \\ a, & M_j = \emptyset. \end{cases}$$

Let  $\mathbf{M}:=(M_1, M_2, \ldots, M_{p-1})$  and denote the composition  $R_{M_{p-1}}\cdots R_{M_2}R_{M_1}(a)$  by  $R_{\mathbf{M}}(a)$ .

Dually, let  $b = B_q | \cdots | B_1 \in P(n)$ . For  $1 \le i < q$ , let  $N_i \subseteq (B_i \smallsetminus \{\min B_i\})$  such that  $\min N_i > \max B_{i+1}$  when  $N_i \ne \emptyset$ . Define the *left-shift*  $N_i$  action

$$L_{N_i}(b) := \begin{cases} B_q | \cdots | B_{i+1} \cup N_i | B_i \smallsetminus N_i | \cdots | B_1, & N_i \neq \emptyset \\ b, & N_i = \emptyset \end{cases}$$

Let  $\mathbf{N} := (N_1, N_2, \dots, N_{q-1})$  and denote the composition  $L_{N_{q-1}} \cdots L_{N_2} L_{N_1}(b)$  by  $L_{\mathbf{N}}(b)$ .

Now given  $\sigma \in \mathcal{V}_e$  and the SCP  $a_{\sigma} \times b_{\sigma}$ , the pair  $R_{\mathbf{M}}(a_{\sigma}) \times L_{\mathbf{N}}(b_{\sigma})$  is a *Complementary Pair* (CP) on  $a_{\sigma} \times b_{\sigma}$ . Define

$$A_{\sigma} \times B_{\sigma} := \bigcup_{\mathbf{M}, \mathbf{N}} \left\{ R_{\mathbf{M}}(a_{\sigma}) \times L_{\mathbf{N}}(b_{\sigma}) \right\}$$

and

(2.2) 
$$\Delta_P(e) := \bigcup_{\sigma \in \mathcal{V}_e} A_\sigma \times B_\sigma.$$

**Example 1.** On the top dimensional cell  $e^2 \subseteq P_3$ ,  $\Delta_P(e^2)$  is the union of

 $\begin{array}{ll} A_{1|2|3}\times B_{1|2|3} = \left\{1|2|3\times 123\right\}, & A_{1|3|2}\times B_{1|3|2} = \left\{1|32\times 13|2\right\}, \\ A_{2|1|3}\times B_{2|1|3} = \left\{21|3\times 2|13,\ 21|3\times 23|1\right\}, & A_{2|3|1}\times B_{2|3|1} = \left\{2|31\times 23|1\right\}, \\ A_{3|1|2}\times B_{3|1|2} = \left\{31|2\times 3|12,\ 1|32\times 3|12\right\}, & A_{3|2|1}\times B_{3|2|1} = \left\{321\times 3|2|1\right\}. \end{array}$ 

**Remark 1.** Note that the matrix representation of a CP introduced in [7] conveniently organizes and systematizes the combinatorial calculation of  $\Delta_P$ . An SCP is represented by a step matrix and a general CP is represented by a derived matrix, given by left-shift and down-shift actions on a step matrix.

When  $X = P_{n+1}$ , Formulas (2.1) and (2.2) are equivalent. The maximal  $(k_1, k_2)$ -subdivision pair with respect to a vertex  $\sigma$  of  $P_{n+1}$  is

(2.3) 
$$\left(\mathbf{I}_{\sigma,1}^{k_1}, \mathbf{I}_{\sigma,2}^{k_2}\right) = \left(\bigcup_{e_1 \in A_{\sigma}} e_1, \bigcup_{e_2 \in B_{\sigma}} e_2\right)$$

**Definition 1.** A positive dimensional face e of  $P_n$  is **non-degenerate** if  $|\theta(e)| = |e|$ . A positive dimensional partition  $a = A_1 | \cdots | A_p \in P(n)$  is **degenerate** if for some j and some k > 0, there exist  $x, z \in A_j$  and  $y \in A_{j+k}$  such that x < y < z; otherwise a is **non-degenerate**. A CP  $\alpha \times \beta$  is **non-degenerate** if  $\alpha$  and  $\beta$  are non-degenerate.

Define 
$$\Delta_K(K_{n+1}) = \Delta_K(\theta(P_n)) := (\theta \times \theta) \Delta_P(P_n)$$
; then  
(2.4)  $\Delta_K(e^{n-1}) = \bigcup_{\substack{\text{non-degenerate CPs}\\\alpha \times \beta \in A_\sigma \times B_\sigma\\\sigma \in S_n}} \{\theta(\alpha) \times \theta(\beta)\}.$ 

## 3. Agreement of $\Delta_K$ and $\Delta'_K$

**Definition 2.** A pair of faces  $a \times b \subseteq K_{n+1} \times K_{n+1}$  is a Matching Pair (MP) if  $a \leq b$  and |a| + |b| = n - 1.

The "magical formula" derived in [5] and [6] is

(3.1) 
$$\Delta'_{K}\left(e^{n-1}\right) = \bigcup_{\substack{\text{MPs of faces}\\a \times b \subseteq K_{n+1} \times K_{n+1}}} \{a \times b\}.$$

Tonks' projection  $\theta$  sends every non-degenerate CP to an MP. The converse is our main result: Every MP is the image of a unique non-degenerate CP under  $\theta$ ; thus  $\Delta'_{K}$  and  $\Delta_{K}$  agree. Our proof of this fact views  $P_{n}$  as a subdivision of  $K_{n+1}$ .

**Definition 3.** Let  $0 \le k < n$ . An associahedral k-cell of  $P_n$  is a k-cell of  $K_{n+1}$ . A subdivision k-cell of  $P_n$  is a k-cell of some associahedral k-cell of  $P_n$ . The maximal (respt. minimal) subdivision k-cell of an associahedral k-cell a, denoted by  $a_{\max}$  (respt.  $a_{\min}$ ), satisfies  $\max a_{\max} = \max a$  (respt.  $\min a_{\min} = \min a$ ). A non-degenerate vertex of  $P_n$  is an associahedral vertex.

Thus a subdivision k-cell of  $P_n$  has the form  $A_1 | \cdots | A_{n-k}$ . In fact, a vertex v of  $P_n$  is associahedral if and only if the (n-q)-cell  $\overrightarrow{v}_q | \cdots | \overrightarrow{v}_1$  is non-degenerate, in which case  $\min \overrightarrow{v}_q > \cdots > \min \overrightarrow{v}_1$ . If k > 0, an associahedral k-cell a is a subdivision k-cell if and only if  $a = a_{\min}$ .

**Proposition 1.** If a is an associahedral k-cell and u is a subdivision k-cell of a, then

- (i)  $a_{\min}$  is non-degenerate.
- (ii) If  $u \neq a_{\min}$ , then u is degenerate and  $u = L_{\mathbf{N}}(a_{\min})$  for some N.
- (iii)  $a_{\min} = R_{\mathbf{M}} (a_{\max})$  for some  $\mathbf{M}$ .

*Proof.* Set p = n - k and consider an associahedral k-cell a of  $P_n$ . If a is also a subdivision k-cell, then  $a = a_{\min} = \theta(a)$  is non-degenerate and  $\mathbf{M} = \emptyset$ . Otherwise, conclusions (i) and (ii) follow from the construction of  $P_n$  as a subdivision of  $K_{n+1}$ . For part (iii), given a subdivision k-cell  $u = A_1 | \cdots | A_p$  of a, let

$$N_p := \{ x \in A_p \setminus \{ \min A_p \} : x > \max A_{p-1} \}.$$

Inductively, if 1 < i < p and  $N_{i+1}$  has been constructed, let  $A'_i := A_i \cup N_{i+1}$  and let

$$N_i := A'_i \setminus \{x \in A'_i \setminus \{\min A'_i\} : x > \max A_{i-1}\}.$$

Then  $a_{\max} = L_{(N_p,...,N_2)}(a_{\min})$ . Set  $\mathbf{M} = (M_1,...,M_{p-1}) := (N_2,...,N_p)$ ; then  $a_{\min} = R_{\mathbf{M}}(a_{\max})$ .

**Example 2.** Consider the associatedral facet  $a = 1|234 \cup 13|24 \cup 14|23 \cup 134|2;$ then  $a_{\min} = 1|234$  is non-degenerate,  $13|24 = L_{\{3\}}(a_{\min}), 14|23 = L_{\{4\}}(a_{\min}), and$  $a_{\max} = 134|2 = L_{\{3,4\}}(a_{\min}).$  Furthermore,  $a_{\min} = 1|234 = R_{\{3,4\}}(134|2).$ 

**Proposition 2.** Let v be an associahedral vertex of  $P_n$  and let  $a = \overrightarrow{v}_q | \cdots | \overrightarrow{v}_1$ . If b is a non-degenerate cell of  $P_n$  such that |b| = |a| and  $\min a \leq \min b$ , then  $b = L_{\mathbf{N}}(a)$  for some  $\mathbf{N}$ .

*Proof.* Let  $a = A_{n-k} | \cdots | A_1$  and let  $r_i = \min A_i$ . Since v is associahedral, it follows that  $r_{n-k} > \cdots > r_1$ . Since  $\min a \le \min b$ , there is a product of p-o increasing transpositions  $\tau := \tau_t \cdots \tau_2 \tau_1$  such that  $\tau(\min a) = \min b$  and  $\tau_i$  preserves the inequality  $r_j > r_{j-1}$  for  $1 \le i \le t$  and  $1 \le j \le n-k$ . Define  $\tau_0 := \mathbf{Id}$  and consider the vertex  $v_i := \tau_{t_i} \cdots \tau_1 \tau_0(\min a)$  for each  $1 \le t_i \le t$ . For each i, there is the (possibly degenerate) cell  $u_i := \overrightarrow{v_i} | \cdots | \overrightarrow{v_i} |$ , where  $q \in \{n-k, n-k+1\}$ . Thus there is the sequence  $\{a = u_0, u_1, \dots, u_t = b\}$  and its subsequence of k-cells  $\{a = u_{i_0}, u_{i_1}, \dots, u_{i_{s-1}}, u_{i_s} = b\}$ . By construction, for  $1 \le j \le s$ , there exists  $n_j \in \underline{n}$  such that  $u_{i_j} = L_{\{n_j\}}(u_{i_{j-1}})$ . For  $1 \le i < s$ , let

$$N_i = \{n_j \in A_i \cup N_1 \cup \dots \cup N_{i-1} : u_{i_j} = L_{\{n_j\}}(u_{i_{j-1}}) \text{ for some } j\}$$

and form the sequence of sets  $\mathbf{N} := (N_{s-1}, ..., N_1)$ . Since b is non-degenerate, the action  $L_{\mathbf{N}}(a)$  is defined and  $L_{\mathbf{N}}(a) = b$ .

Identify a k-face  $F \subset K_{n+1}$  with its corresponding associahedral k-cell of  $P_n$  and label F with its minimal subdivision k-cell  $F_{\min}$ ; then  $\theta(F_{\min}) = F$  (compare Figures 2 and 3).

**Example 3.** Consider the associated ral vertex v = 5|3|1|2|4|6, the associated 3-cell  $a = \overrightarrow{v}_3 |\overrightarrow{v}_2| \overrightarrow{v}_1 = 5|3|1246$  and the non-degenerate 3-cell b = 56|34|12. Then

$$\min a = 5|3|1|2|4|6 < 5|6|3|4|1|2 = \min b,$$

and there is the product of p-o increasing transpositions

$$\tau = \tau_6 \cdots \tau_1 := (3, 6) (4, 6) (1, 6) (2, 6) (1, 4) (2, 4)$$

such that

$$\{v_1 = \tau_1(\min a) = 5|3|1|4|2|6, v_2 = \tau_2(v_1) = 5|3|4|1|2|6, v_3 = \tau_3(v_2) = 5|3|4|1|6|2, v_3 = \tau_3(v_2) = 5|3|4|1|6|2, v_3 = \tau_3(v_3) = 5|3|4|1|6|2, v_3|4|1|6|2, v_3|4|1|6|2|2, v_3|4|1|6|2|2, v_3|4|1|6|2|2, v_3|4|1|6|2|2, v_3|4|1|6|2|2, v_3|4$$

 $v_4 = \tau_4(v_3) = 5|3|4|6|1|2, v_5 = \tau_5(v_4) = 5|3|6|4|1|2, v_6 = \tau_6(v_5) = 5|6|3|4|1|2\}.$ There is the sequence of cells

$$\{u_0 = 5|3|1246, u_1 = 5|3|14|26, u_2 = 5|34|126, u_3 = 5|34|16|2, u_4 = 5|34|16|2, u_5 = 5|34|16|2, u_6 = 5|34|16|2, u_8 = 5|34|16|2, u_8|16|16|2, u_8|16|16|16|2, u_8|16|16|16|2, u_8|16|16|16|16|16|16|16|16|$$

 $u_4 = 5|346|12, u_5 = 5|36|4|12, u_6 = 56|34|12\}$ 

and its subsequence of 3-cells

$$\{u_0 = 5|3|1246, u_2 = 5|34|126, u_4 = 5|346|12, u_6 = 56|34|12\}$$

Thus

$$N_{1} = \{n_{j} \in A_{1} : u_{i_{j}} = L_{\{n_{j}\}}(u_{i_{j-1}}) \text{ for some } j\} = \{4, 6\}, \text{ and}$$

$$N_{j} = \{n_{j} \in A_{j} \mid j \in N_{j} : j \in I_{j} \in I_{j} \} \text{ for some } j\} = \{6\}$$

 $N_2 = \{n_j \in A_2 \cup N_1 : u_{i_j} = L_{\{n_j\}} (u_{i_{j-1}}) \text{ for some } j\} = \{6\}.$ Conclude that  $56|34|12 = L_{(\{4,6\},\{6\})}(5|3|1246).$ 

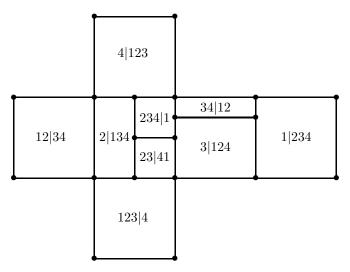

Figure 3: The facets of  $K_5$  labeled with their minimal subdivision 2-cells in  $P_4$ .

**Theorem 1.** Let  $F \times G \subset K_{n+1} \times K_{n+1}$  be an MP. Then  $F_{\min} \times G_{\min} \subset P_n \times P_n$  is a CP and  $F \times G = \theta(F_{\min}) \times \theta(G_{\min})$ . Consequently, the diagonals  $\Delta'_K$  and  $\Delta_K$  agree.

Proof. Let  $\sigma = \max F$ ; then  $F_{\max} = \overleftarrow{\sigma}_1 | \cdots | \overleftarrow{\sigma}_p$  for some p and  $F_{\min} = R_{\mathbf{M}} (F_{\max})$ for some  $\mathbf{M}$  by Proposition 1. Let  $\beta = \overrightarrow{\sigma}_q | \cdots | \overrightarrow{\sigma}_1$  and consider the SCP  $F_{\max} \times \beta$ . Since  $\sigma$  is an associahedral vertex and  $\min \beta \leq \min G_{\min}$  the hypotheses of Proposition 2 is satisfied; hence  $G_{\min} = L_{\mathbf{N}}(\beta)$  for some  $\mathbf{N}$ . Therefore  $F_{\min} \times G_{\min} = R_{\mathbf{M}} (F_{\max}) \times L_{\mathbf{N}}(\beta)$  is a CP and  $F \times G = \theta (F_{\min}) \times \theta (G_{\min})$ .  $\Box$ 

Example 4. Consider the diagonal component

$$F \times G = (\bullet \bullet \bullet) \bullet \bullet \times \bullet (\bullet \bullet (\bullet \bullet))$$

of  $\Delta'_K(K_5)$ . Then  $F = 21|43 \cup 421|3$  is an associahedral 2-cell,  $\sigma = \max F = 4|2|1|3$  is an associahedral vertex,

 $F_{\text{max}} = \overleftarrow{\sigma}_1 | \overleftarrow{\sigma}_2 = 421 | 3, \text{ and } F_{\text{min}} = 21 | 43 = R_{\{4\}} (421 | 3).$ 

Furthermore,

$$\beta = \overrightarrow{\sigma}_{3} | \overrightarrow{\sigma}_{2} | \overrightarrow{\sigma}_{1} = 4 | 2 | 13, \min \beta_{1} = 4 | 2 | 1 | 3 = \max F, \text{ and}$$
$$G_{\min} = L_{\{3\}} (4 | 2 | 13) = 4 | 23 | 1.$$

Thus  $F \times G = \theta (21|43) \times \theta (4|23|1)$ .

Addendum. After this paper was written, B. Delcroix-Oger, G. Laplante-Anfossi, V. Pilaud, and K. Stoeckl proved that  $\Delta_P$  can be recovered from  $\Delta'_P$  by an appropriate choice of chambers in the fundamental hyperplane arrangements of the permutahedra (see [2]). The fact that all known diagonals on the associahedra agree (up to mirror symmetry) follows immediately.
